ACCURATE MEASUREMENTS OF THE $J = 1 - 0$ TRANSITIONS OF H_2D^+ AND HD_2^+ USING LASER-INDUCED REACTIONS AND DETERMINATION OF SPECTROSCOPIC PARAMETERS FOR H_2D^+

OSKAR ASVANY, HOLGER S. P. MÜLLER, OLIVER RICKEN, MARTINA C. WIEDNER, THOMAS F. GIESEN, STEPHAN SCHLEMMER, *I. Physikalisches Institut, Universität zu Köln, 50937 Köln, Germany*.

The method of laser-induced reaction[a] has been used for the first time to detect rotational transitions. The astronomically important $1_{01} - 0_{00}$ and $1_{11} - 0_{00}$ transitions of H_2D^+ and HD_2^+, respectively, have been recorded by observing the enhancement of their D/H isotope exchange reactions with p-H_2 upon rotational excitation in a cryogenic multipole ion trap. While the frequency for HD_2^+ is in good agreement with a previous, unpublished result,[b] but more accurate, the frequency for H_2D^+ is some 60 MHz lower than the value from the same unpublished source (*b*).

The present H_2D^+ frequency has been fit together with previously published pure rotational transitions and with infrared ground state combination differences (GSCDs).[c] Starting values for spectroscopic parameters were derived from energies up to $J = K_a = 7$ calculated ab initio[d] because of the smallness of the data set. Since the molecular ion is fairly floppy, the Hamiltonian has been expanded in Euler functions[e] up to 6th order. Omitting one GSCD because of a large residual, the remaining GSCDs were reproduced to almost $0.002\,\mathrm{cm}^{-1}$ releasing only 7 parameters. Thus, for the first time this IR spectroscopic data has been reproduced within experimental uncertainties. The pure rotational transitions were fit overall within the reported experimental uncertainties. In Ref. *c* the wrong $1_{01} - 0_{00}$ transition frequency required 11 parameters to fit the pure rotational transitions within experimental uncertainties, albeit with somewhat larger residuals for the GSCDs than in the present work.
