

# Basic Physics Processes in a Sodium Iodide (NaI) Calorimeter

NaI is a “scintillator”. As a charged particle traversing the NaI it loses energy. The energy is absorbed by the molecules and puts the NaI molecules into an excited state. NaI gives off light (“scintillates”) when it de-excites back to the ground state.

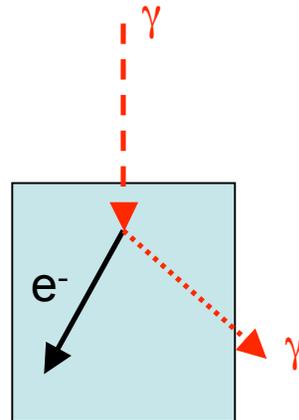

The amount of light given off by NaI is proportional to the amount energy absorbed. The light yield is  $\sim 1$  photon produced per 100 eV deposited in NaI (1 MeV =  $10^4$   $\gamma$ 's). However, not all  $\gamma$ 's are collected as the efficiency of the photocathode is  $\sim 20\%$ .

Photoelectric Effect  
 $\gamma$  absorbed by material  
electron ejected

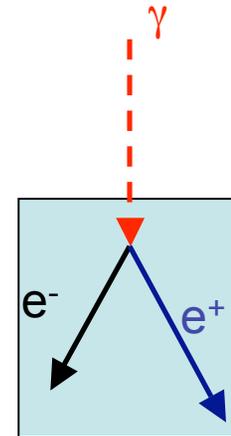

$h\nu < 0.05 \text{ MeV}$

Compton Scattering  
 $\gamma e^- \rightarrow \gamma e^-$   
“elastic scattering”

$0.05 < h\nu < 10 \text{ MeV}$

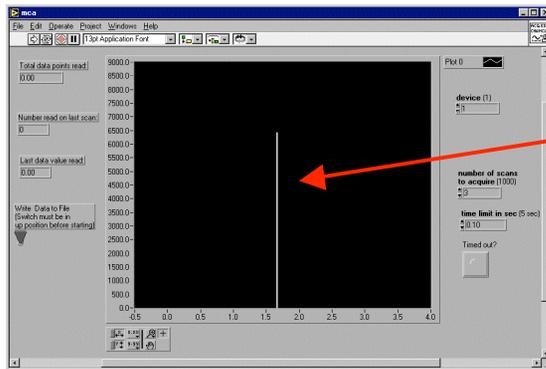

Pair Production  
 $\gamma \rightarrow e^+ e^-$   
creates anti-matter

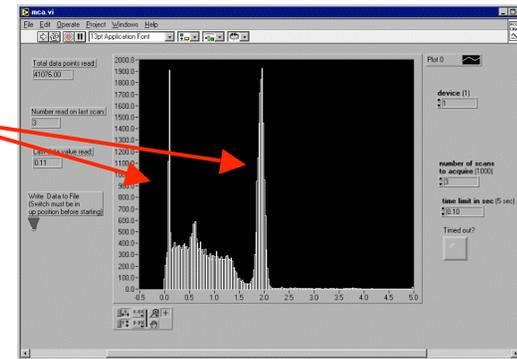

$h\nu > 10 \text{ MeV}$   
 $\gamma$ -ray must have  $E > 2m_e$

# How do we get a PEAK in the energy spectrum?

A peak in the energy spectrum corresponds to the case when all of the  $\gamma$ -ray's energy is absorbed in the NaI calorimeter.

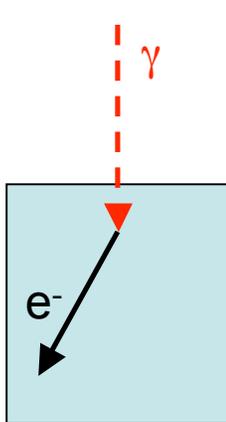

perfect energy resolution  
all  $\gamma$  energy totally absorbed

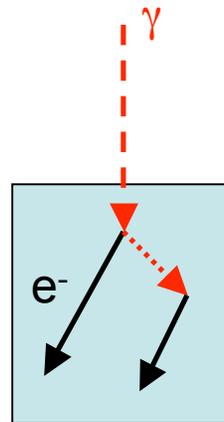

actual energy resolution  
not all  $\gamma$  energy totally absorbed

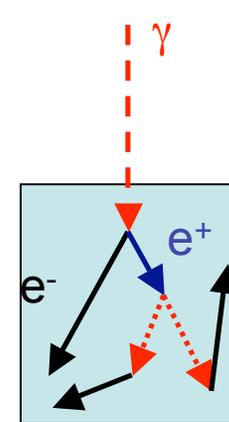

peaks

Photoelectric effect  
and electron stops  
in NaI.

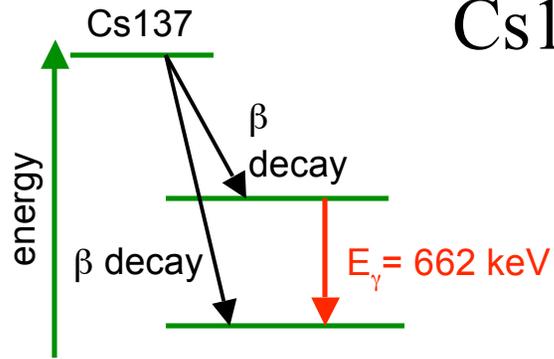

Compton scatter followed  
by photoelectric effect

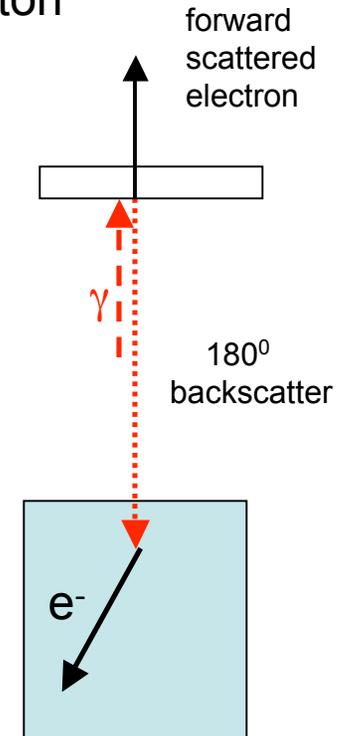

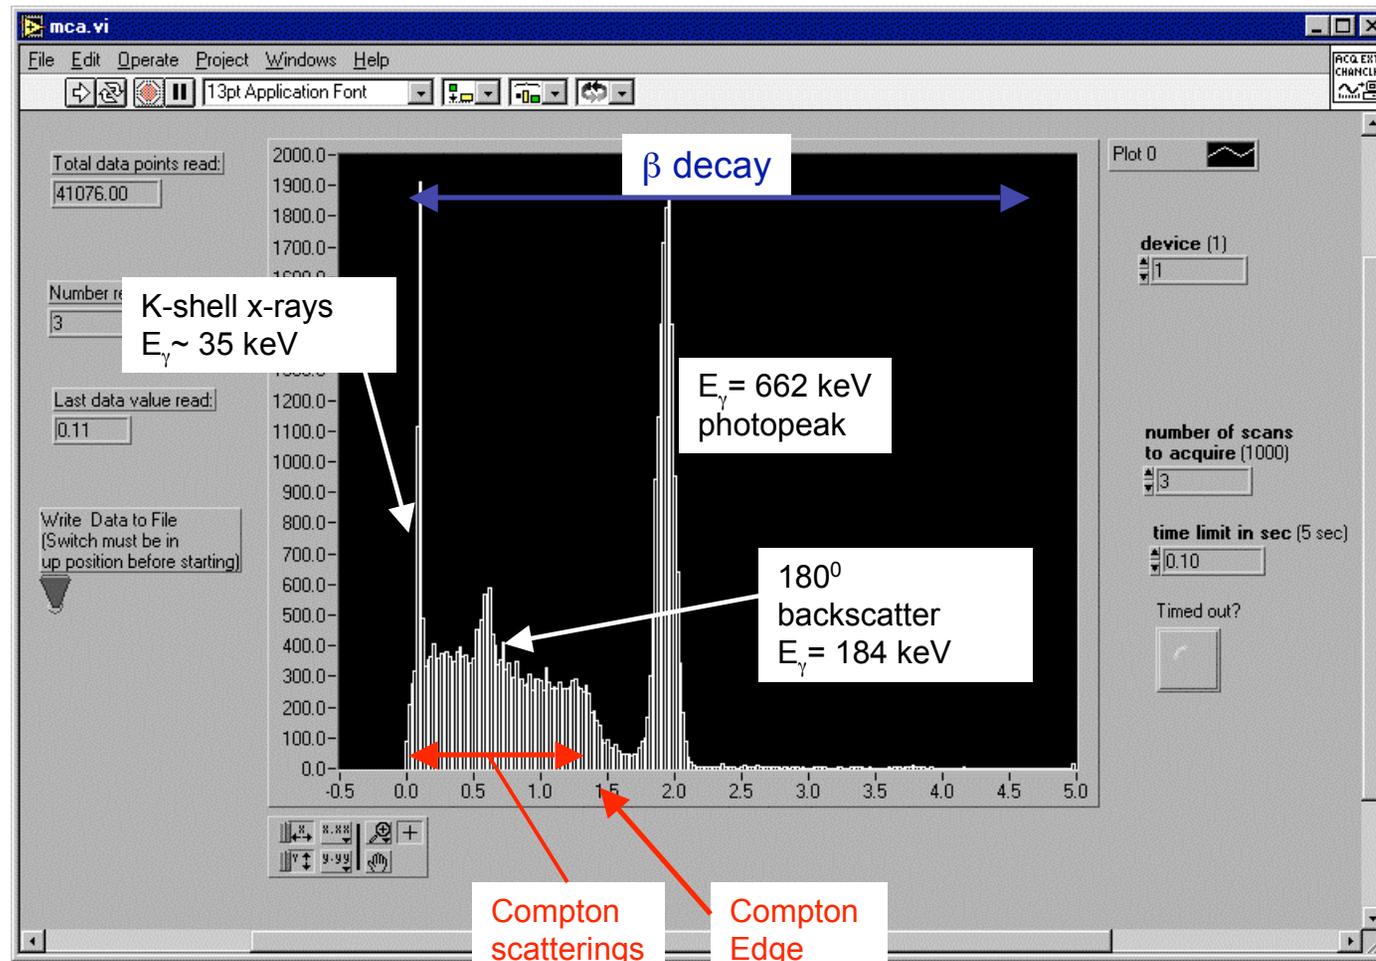

Pair production  
 $e^-$  is absorbed in NaI  
 $e^+$  annihilates into 2  $\gamma$ 's  
 $\gamma$ 's undergo photoelectric effect

# Cs137 $\gamma$ -ray Spectrum

$\beta$  decay gives off electrons with a range of energies  
 $E_{\text{max}} = 514 \text{ keV}, 1170 \text{ keV}$   
 $\gamma$  decay gives off a monochromatic photon  
 $E = 662 \text{ keV}$

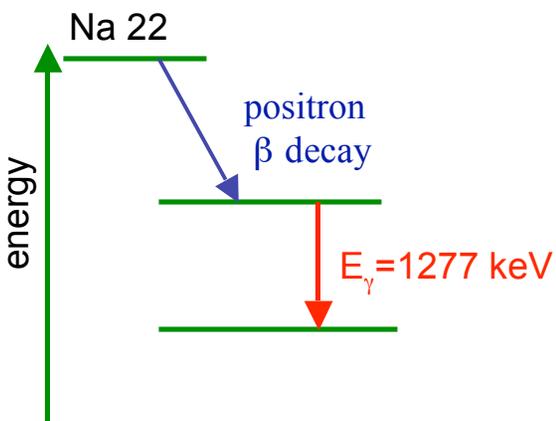

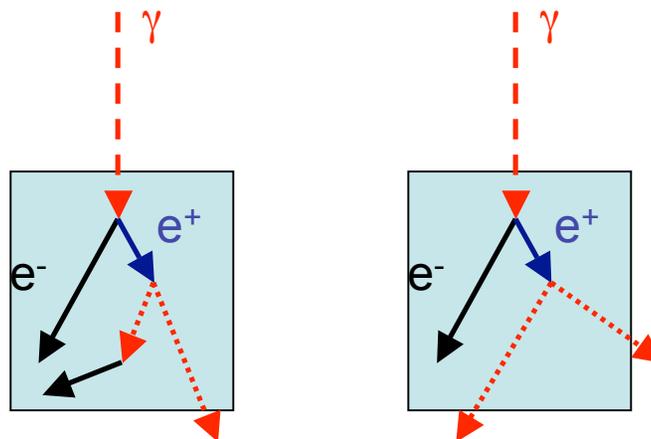

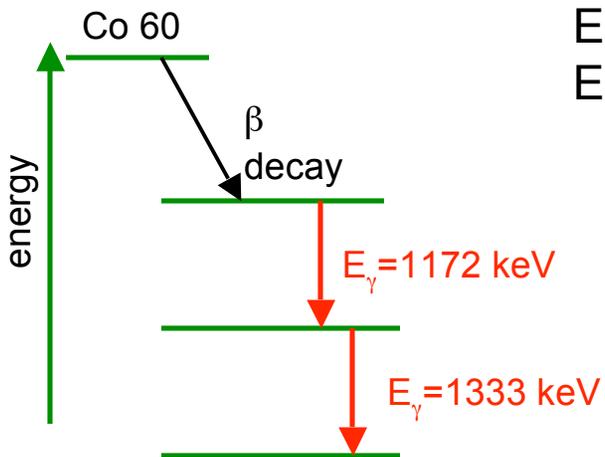

# Co60 and Na22

Both Co60 and Na22 have complicated spectra since their  $\gamma$ 's have enough energy to undergo pair production.

Will have "escape" peaks from positron annihilation

$$E = E_{\gamma} - (\text{rest energy of electron})$$

$$E = E_{\gamma} - 2 \times (\text{rest energy of electron})$$

Na22 gives off a positron which will annihilate and produce 2  $\gamma$ 's. But only one  $\gamma$  will be detected!
