April 15, 2009

Abstract

The reaction-diffusion system modeling the dorsal-ventral patterning during the zebrafish embryo development, developed in [Y.-T. Zhang, A.D. Lander, Q. Nie, Journal of Theoretical Biology, 248 (2007), 579–589] has multiple steady state solutions. In this paper, we describe the computation of seven steady state solutions found by discretizing the boundary value problem using a finite difference scheme and solving the resulting polynomial system using algorithms from numerical algebraic geometry. The stability of each of these steady state solutions is studied by mathematical analysis and numerical simulations via a time marching approach. The results of this paper show that three of the seven steady state solutions are stable and the organizer of the zebrafish embryo plays an important role in the selection of the steady state pattern in this multi-stability system.

1 Introduction

The proper functioning of tissues and organs requires that each cell differentiates appropriately for its position. In many cases, the positional information that instructs cells about their prospective fates is conveyed by concentration gradients of morphogens bound to cellular receptors. Morphogens are signaling molecules that, when bound to receptors, assign different cell fates at different concentrations [8, 10]. Morphogen action is of special importance in understanding development, as it is a highly efficient way for a population of uncommitted cells in an embryo to create complex patterns of gene expression in space [5].

In [11], a nonlinear reaction-diffusion model on both three-dimensional and a simplified one-dimensional spatial domains was developed for computational analysis of BMP morphogen gradient formation in dorsal-ventral patterning of the zebrafish embryo. The model predicts that the dorsal organizer of the zebrafish embryo plays a key role in forming a stable non-homogeneous morphogen gradient, and the prediction agrees well with the existing biological experiments [6]. We briefly describe the model in the following paragraphs.

Consider the dorsal-ventral axis of the zebrafish embryo. The model simplifies it to a one-dimensional segment \( 0 \leq x \leq x_{\text{max}} \) with the dorsal organizer being located at the corner of the dorsal region, as shown in Figure (1).

![Figure 1.1: The simplified one dimensional geometry of wild type zebrafish embryo. The dorsal organizer is located at the end with the size \( \frac{1}{8} \) of the whole embryo.](image)

Let \([L]\) and \([LR]\) denote the concentration of the morphogen BMP and the concentration of BMP-receptor complexes (to which BMP signaling is assumed to be proportional), respectively. The concentration of the free molecule Chordin (an inhibitor of BMP) and the concentration of BMP-Chordin complex are denoted by \([C]\) and \([LC]\), respectively. Let \(R_0\) denote the total receptor concentration and let \(D_L\), \(D_C\), and \(D_{LS}\) represent the three diffusion coefficients for BMP, Chordin, BMP-Chordin complexes, respectively. The values \(k_{\text{on}}, k_{\text{off}}, k_{\text{deg}}, \eta_{\text{on}}, \eta_{\text{off}},\) and \(\tau\) are the binding and degradation rates for BMP, Chordin, and their complexes. With
this notation, the reaction-diffusion model that is formulated in [11] is as follows:

\[
\begin{align*}
\frac{\partial[L]}{\partial t} &= D_L \frac{\partial^2[L]}{\partial x^2} - k_{on}[L](R_0 - [LR]) + k_{off}[LR] - j_{on}[L][C] + (j_{off} + \tau)[LC] + V_L; \\
\frac{\partial[LR]}{\partial t} &= k_{on}[L](R_0 - [LR]) - (k_{off} + k_{deg})[LR]; \\
\frac{\partial[LC]}{\partial t} &= D_{LS} \frac{\partial^2[LC]}{\partial x^2} + j_{on}[L][C] - (j_{off} + \tau)[LC]; \\
\frac{\partial[C]}{\partial t} &= D_C \frac{\partial^2[C]}{\partial x^2} - j_{on}[L][C] + j_{off}[LC] + V_C,
\end{align*}
\]

(1.1)

where \( V_C \) and \( V_L \) are the production rates of molecules Chordin and BMP, respectively, defined by

\[
V_C = V_{C_{\text{min}}} + \frac{V_{C_{\text{max}} - V_{C_{\text{min}}}}}{1 + \gamma_C[LR]} + \begin{cases} V_{C_{\text{org}}}e^{-at}, & \text{if } x \geq \frac{7}{8}x_{\text{max}}; \\
0, & \text{otherwise.}
\end{cases}
\]

(1.2)

\[
V_L = V_{L_{\text{min}}} + \frac{V_{L_{\text{max}} - V_{L_{\text{min}}}}}{1 + \gamma_L[LR]^{-1}} + V_{L_{\text{mat}}}e^{-bt}.
\]

(1.3)

The terms \( V_{C_{\text{org}}}e^{-at} \) and \( V_{L_{\text{mat}}}e^{-bt} \) represent the maternal production rates of Chordin and BMP [11].

The system (1.1) is subjected to the no-flux boundary conditions

\[
\frac{\partial[L]}{\partial x} = \frac{\partial[LC]}{\partial x} = \frac{\partial[C]}{\partial x} = 0 \quad \text{for } x = 0, x_{\text{max}}.
\]

(1.4)

Although no boundary condition is assumed for \([LR]\), the initial data for \([LR]\) does satisfy the no-flux boundary condition. Thus, by using the system (1.1), we also have

\[
\frac{\partial[LR]}{\partial x} = 0 \quad \text{for } x = 0, x_{\text{max}}.
\]

(1.5)

Parameter studies were performed in [11] and, with the following biological reasonable parameters

\[
\begin{align*}
x_{\text{max}} &= 0.088 \text{cm}, \\
D_L &= D_{LS} = D_C = 8.5 \times 10^{-7} \text{cm}^2 \text{s}^{-1}, \\
R_0 &= 3.0 \mu M, \\
j_{on} &= 10 \mu M^{-1} \text{s}^{-1}, \\
\tau &= 0.01 \text{s}^{-1}, \\
k_{on} &= 0.4 \mu M^{-1} \text{s}^{-1}, \\
k_{off} &= 4 \times 10^{-6} \text{s}^{-1}, \\
j_{off} &= 1.0 \times 10^{-5} \text{s}^{-1}, \\
k_{deg} &= 5.0 \times 10^{-4} \text{s}^{-1}, \\
V_{C_{\text{min}}} &= 8.0 \times 10^{-4} \mu M \text{s}^{-1}, \\
V_{C_{\text{org}}} &= 6.68 \times 10^{-1} \mu M \text{s}^{-1}, \\
a &= 0.0167 \text{s}^{-1}, \\
V_{C_{\text{max}}} &= 8.0 \times 10^{-2} \mu M \text{s}^{-1}, \\
V_{L_{\text{min}}} &= 1.0 \times 10^{-5} \mu M \text{s}^{-1}, \\
V_{L_{\text{max}}} &= 6.0 \times 10^{-3} \mu M \text{s}^{-1}, \\
V_{L_{\text{org}}} &= 5.01 \times 10^{-2} \mu M \text{s}^{-1}, \\
\gamma_C &= 10 \mu M^{-1}, \\
V_{L_{\text{max}}} &= 5.01 \times 10^{-2} \mu M \text{s}^{-1}, \\
b &= 0.0167 \text{s}^{-1}, \\
\end{align*}
\]

(1.6)
a non-homogeneous spatial BMP morphogen gradient is formed. The high concentration region of BMP-receptor complex will develop into the ventral tissue of the zebrafish, and the low concentration region will become the dorsal part of the fish.

In this paper, we study multiple steady state solutions of the reaction-diffusion system (1.1). We obtain seven steady state solutions by numerically solving the corresponding boundary value problem using a combination of a finite difference discretization of the differential equation and numerical algebraic geometric methods for solving the resulting nonlinear algebraic system. The stability of each steady state solution is studied using mathematical analysis and numerical simulations via a time marching approach. We show that three of the seven steady state solutions are stable and the organizer of the zebrafish embryo plays an important role in the selection of the steady state pattern in this multi-stability system.

Yong-Tao Zhang proposed the problem of finding stable solutions for the zebra fish model in this article. His student Yuan Liu approached the problem by looking at the limits of the diffusion problem by time-marching methods. Andrew Sommese proposed solving completely the nonlinear polynomial system associated to the stationary problem for a modest grid, choosing appropriate solutions from those found, and refining them to a larger grid. The work of setting up the polynomial systems and deciding how to refine was done primarily by his student Jonathan Hauenstein with contributions by Sommese’s student Wenrui Hao. Bei Hu gave guidance on numerous issues connected with the system and modifications for numerical solving. He also led the investigation into the stability of the solutions found, with the main work on numerical verification done by Yuan Liu followed by Jonathan Hauenstein.

2 Multiple steady state solutions

The steady state solutions of the system (1.1) satisfy the following boundary value problem:

\[
\begin{align*}
0 &= D_L \frac{\partial^2[L]}{\partial x^2} - k_{on}[L](R_0 - [LR]) + k_{off}[LR] - j_{on}[L][C] + (j_{off} + \tau)[LC] + V_L; \\
0 &= k_{on}[L](R_0 - [LR]) - (k_{off} + k_{deg})[LR]; \\
0 &= D_L S \frac{\partial^2[LC]}{\partial x^2} + j_{on}[L][C] - (j_{off} + \tau)[LC]; \\
0 &= D_C \frac{\partial^2[C]}{\partial x^2} - j_{on}[L][C] + j_{off}[LC] + V_C,
\end{align*}
\]  
(2.1)

where

\[0 = x_{\text{min}} \leq x \leq x_{\text{max}} = 0.088cm, \]  
(2.2)

\[V_C = V_{C\text{min}} + \frac{V_{C\text{max}} - V_{C\text{min}}}{1 + \gamma_C[LR]}, \]  
(2.3)

and

\[V_L = V_{L\text{min}} + \frac{V_{L\text{max}} - V_{L\text{min}}}{1 + \gamma_L[LR]^{-1}}, \]  
(2.4)
subjected to the no-flux boundary conditions
\[
\frac{\partial[L]}{\partial x} = \frac{\partial[LC]}{\partial x} = \frac{\partial[C]}{\partial x} = 0. \tag{2.5}
\]

The following section describes the computation of the seven steady state solutions we obtained for system (2.1).

2.1 Computing multiple steady state solutions

Steady state solutions to the boundary value problem (2.1) were found by discretizing and computing all solutions of the resulting system of equations using the software package Bertini [1, 2].

Observe that system (2.1) can be simplified by replacing the first equation with the sum of the first three equations and by replacing the last equation with the sum of the last two equations. Upon clearing denominators, we obtain the boundary value system

\[
\begin{align*}
0 &= ([LR] + \gamma_L) \left( D_L \frac{\partial^2[L]}{\partial x^2} - k_{deg}[LR] + D_{LS} \frac{\partial^2[LC]}{\partial x^2} + V_{Lmin} \right) + (V_{Lmax} - V_{Lmin})[LR]; \\
0 &= k_{on}[L](R_0 - [LR]) - (k_{off} + k_{deg})[LR]; \\
0 &= D_{LS} \frac{\partial^2[LC]}{\partial x^2} + j_{on}[L][C] - (j_{off} + \tau)[LC]; \\
0 &= (1 + \gamma_C[LR]) \left( D_C \frac{\partial^2[C]}{\partial x^2} - \tau[LC] + V_{Cmin} \right) + V_{Cmax} - V_{Cmin}.
\end{align*}
\tag{2.6}
\]

where \(0 = x_{\min} \leq x \leq x_{\max} = 0.088\text{cm}\) with boundary conditions (2.5). This system is discretized using the second order central difference scheme for the interior conditions and left- and right-sided second order difference schemes for the boundary conditions with \(\Delta x = \frac{x_{\max} - x_{\min}}{N}\), where \(N \geq 3\). The boundary conditions for \([L]\) become

\[
\begin{align*}
3[L]_0 &= 4[L]_1 - [L]_2, \\
3[L]_N &= 4[L]_{N-1} - [L]_{N-2},
\end{align*}
\]

with similar conditions for \([LC]\) and \([C]\).

Using the system (2.6), the boundary conditions for \([LR]\) are

\[
\begin{align*}
k_{on}[L]_0(R_0 - [LR]_0) &= (k_{off} + k_{deg})[LR]_0, \\
k_{on}[L]_N(R_0 - [LR]_N) &= (k_{off} + k_{deg})[LR]_N.
\end{align*}
\]

As suggested by (1.5), we could also utilize the no-flux boundary condition

\[
\begin{align*}
3[LR]_0 &= 4[LR]_1 - [LR]_2, \\
3[LR]_N &= 4[LR]_{N-1} - [LR]_{N-2}.
\end{align*}
\]

Either way, since (2.6) does not depend upon \(\frac{\partial^2[LR]}{\partial x^2}\), \([LR]_0\) and \([LR]_N\) only appear in the boundary conditions for \([LR]\) in the discretized system. This means that they can be computed after the other values are known.
Table 2.1: Summary of solving the discretized system for $3 \leq N \leq 9$

With these simplifications, the discretized polynomial system that we solved consisted of $4(N-1)$ quadratic polynomials in $4(N-1)$ variables. For $3 \leq N \leq 9$, we computed all solutions of this polynomial system using Bertini [1, 2]. Bertini is a software package in the field of numerical algebraic geometry that implements homotopy continuation based algorithms to numerically compute all solutions of polynomial systems over $\mathbb{C}$. For more information on homotopy continuation and the field of numerical algebraic geometry, see [7].

As suggested by (2.6), this polynomial system has an obvious linear product structure [9], one such linear decomposition, for $i = 1, \ldots, N$, is

$$\begin{align*}
\{1, [LR]_i\} \times \{1, [LR]_i, [L]_{i-1}, [L]_i, [L]_{i+1}, [LC]_{i-1}, [LC]_i, [LC]_{i+1}\} \\
\{1, [LR]_i\} \times \{1, [L]_i\} \\
\{1, [L]_i\} \times \{1, [C]_i, [LC]_{i-1}, [LC]_i, [LC]_{i+1}\} \\
\{1, [LR]_i\} \times \{1, [LC]_i, [C]_{i-1}, [C]_i, [C]_{i+1}\}.
\end{align*}$$

This linear product structure reduces the bound on the number of isolated solutions over $\mathbb{C}$ for the discretized system from its total degree bound of $2^{4(N-1)} = 16^{N-1}$ to $5^{N-1}$. This bound is nearly sharp with our computations revealing that there are actually $5^{N-1} - 3^{N-1}$ solutions over $\mathbb{C}$.

For $3 \leq N \leq 9$, we used Bertini v1.1.1 with adaptive precision tracking [3, 4] to solve the discretized polynomial system. We ran Bertini on a cluster consisting of a manager that uses one core of a Xeon 5410 processor and up to 25 computing nodes, each containing two Xeon 5410 processors running 64-bit Linux, i.e., each node consists of 8 processing cores. Table 2.1 lists the linear product bound, the number of solutions over $\mathbb{C}$, the number of solutions over $\mathbb{R}$, the number of computing nodes utilized, and the time needed to compute all solutions of the discretized polynomial system.

Using the real solutions, we constructed an approximate solution of the discretized system with 80 grid points by using a cubic spline. Each of these approximate solutions was refined and the resulting solutions that contained negative real values were discarded. This process yielded seven positive real solutions.

3 Stability of the steady state solutions

The analysis of the steady state solutions utilized eigenvalue computations and numerical simulations via time marching. The eigenvalue analysis was computed using the non-dimensionalized system described in the next section.
3.1 The non-dimensionalized system

To non-dimensionalize system (1.1), we introduced the following normalized quantities:

\[ T = \frac{D}{x_{\text{max}}^2} t, \quad X = \frac{x}{x_{\text{max}}}, \quad (3.1) \]

\[ \{f_L, g_L, h_L, f_S, h_S, \tau_S\} = \frac{x_{\text{max}}^2}{D} \{k_{\text{off}}, k_{\text{deg}}, k_{\text{on}} R_0, j_{\text{off}}, j_{\text{on}} R_0, \tau\}, \quad (3.2) \]

\[ \{A, B, C, S\} = \frac{1}{R_0} \{[L], [LR], [LC], [C]\}, \quad (3.3) \]

\[ \{W_{\text{Cmin}}, W_{\text{Cmax}}, W_{\text{Corg}}, W_{L\text{min}}, W_{L\text{max}}, W_{L\text{mat}}\} = \frac{x_{\text{max}}^2}{DR_0} \{V_{\text{Cmin}}, V_{\text{Cmax}}, V_{\text{Corg}}, V_{L\text{min}}, V_{L\text{max}}, V_{L\text{mat}}\}, \quad (3.4) \]

\[ \{d_L, d_LS, d_C\} = \frac{1}{D} \{D_L, D_LS, D_C\}, \quad \gamma_C = \frac{\gamma_{C R_0}}{\tau_L} = \frac{\gamma_{L R_0}}{\tau_L}, \quad (3.5) \]

where \( D \) is the maximum of \( D_L, D_LS \) and \( D_C \) in (1.6), namely

\[ D = 8.5 \times 10^{-7} \text{cm}^2 \text{s}^{-1}. \]

With these normalized quantities, we rewrote the system (1.1) in the following dimensionless form:

\[
\begin{aligned}
\frac{\partial A}{\partial T} &= d_L \frac{\partial^2 A}{\partial X^2} - h_L A (1 - B) + f_L B - h_S A S + (f_S + \tau_S) C + W_L; \\
\frac{\partial B}{\partial T} &= h_L A (1 - B) - (f_L + g_L) B; \\
\frac{\partial C}{\partial T} &= d_LS \frac{\partial^2 C}{\partial X^2} + h_S A S - (f_S + \tau_S) C; \\
\frac{\partial S}{\partial T} &= d_C \frac{\partial^2 S}{\partial X^2} - h_S A S + f_S C + W_C,
\end{aligned}
\]

where

\[ 0 \leq X \leq 1 \]

and

\[ W_C = W_{\text{Cmin}} + \frac{W_{\text{Cmax}} - W_{\text{Cmin}}}{1 + \gamma_C B} + \begin{cases} W_{\text{Corg}} e^{-PT}, & \text{if } X \geq \frac{7}{8}; \\
0, & \text{otherwise.} \end{cases} \quad (3.7) \]

with

\[ P = \frac{x_{\text{max}}^2}{D} a, \quad (3.8) \]

and

\[ W_L = W_{L\text{min}} + \frac{W_{L\text{max}} - W_{L\text{min}}}{1 + \gamma_L B^{-1}} + W_{L\text{mat}} e^{-QT}, \quad (3.9) \]

with

\[ Q = \frac{x_{\text{max}}^2}{D} b. \quad (3.10) \]
The non-dimensionalized parameters corresponding to those in (1.6) are:

\[ d_L = d_{LS} = d_C = 1, \quad h_L = 1.0924 \times 10^4, \]
\[ f_L = 0.0364, \quad h_S = 2.7310 \times 10^5, \]
\[ f_S = 0.0910, \quad \tau_S = 91.0326, \]
\[ g_L = 4.5516, \quad W_{C_{\text{min}}} = 2.4275, \]
\[ W_{C_{\text{max}}} = 242.7536, \quad W_{C_{\text{org}}} = 2.0270 \times 10^3, \]
\[ \gamma_C = 30, \quad P = 152.0244, \]
\[ W_{L_{\text{min}}} = 0.0303, \quad W_{L_{\text{max}}} = 18.2065, \]
\[ \gamma_L = 3.3333, \quad W_{L_{\text{mat}}} = 152.0244, \quad Q = 152.0244. \]

### 3.2 Eigenvalue analysis of the steady state solutions

The exponential terms in (3.7) and (3.9) correspond to the maternal production terms for the original system (1.1). These terms decay exponentially with \( Q = P = 152.0244 \), as shown in (3.11). Since we are considering the local stability of the steady state solutions, we drop the maternal production terms in the analysis of (3.6).

Assuming that

\[
\begin{pmatrix}
A \\
B \\
C \\
S
\end{pmatrix} = \begin{pmatrix}
A_0 \\
B_0 \\
C_0 \\
S_0
\end{pmatrix} + \varepsilon \begin{pmatrix}
A_1 \\
B_1 \\
C_1 \\
S_1
\end{pmatrix} + O(\varepsilon^2),
\]

the linearized system is

\[
\begin{cases}
A_{1T} = A_{1XX} - h_LA_1(1 - B_0) + h_LA_0B_1 + f_LB_1 - h_SA_1S_0 - h_SA_0S_1 + (f_S + \tau_S)C_1 \\
B_{1T} = h_LA_1(1 - B_0) - h_LA_0B_1 - (f_L + g_L)B_1; \\
C_{1T} = C_{1XX} + h_SA_1S_0 + h_SA_0S_1 - (f_S + \tau_S)C_1; \\
S_{1T} = S_{1XX} - h_SA_1S_0 - h_SA_0S_1 + f_SC_1 - B_1 \frac{(W_{C_{\text{max}}} - W_{C_{\text{min}}})\gamma_C}{(1 + \gamma_CB_0)^2}.
\end{cases}
\]

For

\[
Y(X, T) = \begin{pmatrix}
A_1(X, T) \\
B_1(X, T) \\
C_1(X, T) \\
S_1(X, T)
\end{pmatrix},
\]

the system (3.12) can be written as

\[
\frac{\partial Y}{\partial T} = \begin{pmatrix}
1 & 0 \\
0 & 1 \\
0 & 1
\end{pmatrix} Y_{XX} + M \cdot Y, \quad (3.13)
\]
where

\[
M = \begin{pmatrix}
-h_L(1 - B_0) - h_S S_0 & h_L A_0 + f_L + \frac{(W_{L \text{max}} - W_{L \text{min}}) \gamma_L}{(\gamma_L + B_0)^2} & f_S + \tau_S & -h_S A_0 \\
-h_L(1 - B_0) & -h_L A_0 - (f_L + g_L) & 0 & 0 \\
h_S S_0 & 0 & -(f_S + \tau_S) & h_S A_0 \\
-h_S S_0 & -(W_{C \text{max}} - W_{C \text{min}}) \gamma_C & f_S & -h_S A_0
\end{pmatrix}.
\]

The seven steady state solutions consist of a constant solution and six non-constant solutions. The following establishes that the constant solution is unstable and three of the six non-constant solutions are also unstable.

I) Constant solution analysis.

For the constant solution, the vector \((A_0, B_0, C_0, S_0)\) is constant as well as the matrix \(M\). With the no-flux boundary conditions and separation of variables, we can always write

\[
Y(X, T) = \sum_{n=0}^{\infty} \overrightarrow{b_n}(T) \cos(n\pi X), \ 0 \leq X \leq 1.
\]

The system (3.13) yields

\[
\frac{\partial}{\partial T} \overrightarrow{b_n}(T) = \left[ \begin{array}{c}
-(n\pi)^2 \\
0 \\
-(n\pi)^2 \\
-(n\pi)^2
\end{array} \right] + M \overrightarrow{b_n}(T), \ n = 0, 1, 2 \ldots \quad (3.14)
\]

Since \(\{\cos(n\pi X)\}\) forms an orthogonal basis, the system (3.12) is asymptotically stable at the constant solution if and only if each system (3.14) is asymptotically stable for all \(n = 0, 1, 2 \ldots \).

For each \(n\), let

\[
A_n = \left[ \begin{array}{c}
-(n\pi)^2 \\
0 \\
-(n\pi)^2 \\
-(n\pi)^2
\end{array} \right] + M.
\]

The ODE theory implies that the system (3.14) is stable if and only if each of the four eigenvalues for each \(A_n\) have negative real part. Evaluating \(M\) at the non-dimensionalized constant solution, both \(A_1\) and \(A_2\) have a real positive eigenvalue, namely, 0.3373 and 0.3634, respectively, yielding that the constant solution is not stable.

II) General solution analysis

By separation of variables, we can write

\[
Y(X, T) = e^{\lambda T} J(X).
\]

The system (3.13) yields that

\[
BJ = \begin{pmatrix}
1 & 0 \\
0 & 1 \\
0 & 0
\end{pmatrix} J_{XX} + M \cdot J = \lambda J
\]
It follows that the only spectrum for \( B \) eigenvalues. Note that \( \mu = 0 \) and we calculate the numerical solutions of the eigenvalue problem. With grid points \( 0 = X_0, X_1, ..., X_{N-1}, X_N = 1 \), here, \( N = 320 \) in our computation, the boundary conditions yield

\[
J(X_0) = \frac{4J(X_1) - J(X_2)}{3}, \\
J(X_N) = \frac{4J(X_{N-1}) - J(X_{N-2})}{3}.
\]

Then the eigenvalue problem is discretized as

\[
\begin{pmatrix}
  n^2 & 0 & 0 & \cdots & 0 \\
  0 & n^2 & 0 & \cdots & 0 \\
  \vdots & \vdots & \vdots & \ddots & \vdots \\
  0 & 0 & 0 & \cdots & n^2
\end{pmatrix}
\begin{pmatrix}
  J(X_{k+1}) \\
  J(X_k) \\
  J(X_{k-1}) \\
  \vdots \\
  J(X_N)
\end{pmatrix} - 2J(X_k) + J(X_{k-1}) + M(X_k) \cdot J(X_k) = \lambda J(X_k),
\]

or, more specifically,

\[
\begin{aligned}
n^2(J_1(X_{k+1}) - 2J_1(X_k) + J_1(X_{k-1})) + \sum_{j=1}^{4} m_{1j}(X_k)J_j(X_k) &= \lambda J_1(X_k), & 1 \leq k \leq N - 1; \\
\sum_{j=1}^{4} m_{2j}(X_k)J_j(X_k) &= \lambda J_2(X_k), & 0 \leq k \leq N; \\
n^2(J_3(X_{k+1}) - 2J_3(X_k) + J_3(X_{k-1})) + \sum_{j=1}^{4} m_{3j}(X_k)J_j(X_k) &= \lambda J_3(X_k), & 1 \leq k \leq N - 1; \\
n^2(J_4(X_{k+1}) - 2J_4(X_k) + J_4(X_{k-1})) + \sum_{j=1}^{4} m_{4j}(X_k)J_j(X_k) &= \lambda J_4(X_k), & 1 \leq k \leq N - 1.
\end{aligned}
\]
Letting

\[
V = \begin{pmatrix}
J_2(X_0) \\
J_1(X_1) \\
J_2(X_1) \\
J_3(X_1) \\
J_4(X_1) \\
\vdots \\
J_1(X_{N-1}) \\
J_2(X_{N-1}) \\
J_3(X_{N-1}) \\
J_4(X_{N-1}) \\
J_2(X_N)
\end{pmatrix},
\]

and denoting the coefficients matrix of (3.18) by \( G \), we can rewrite (3.18) in the matrix form

\[
G \cdot V = \lambda \cdot V.
\] (3.19)

So finally, the eigenvalue problem reduces to calculate the eigenvalues of the matrix \( G \).

For each of the seven steady state solutions on 320 grid points, we computed the matrix \( G \) and its eigenvalues, and obtained the following results:

**Solutions 1 and 2** These two solutions have the same eigenvalues. All the eigenvalues have negative real parts as shown in Figure 3.1. The eigenvalue of each solution with maximum real part is \(-0.1455 \pm 1.47146i\).

![Figure 3.1: The distribution of the eigenvalues on the complex plane for solutions 1 and 2](image)

**Solution 3 (constant solution)** To verify our computations, we recomputed the eigenvalues for the constant solution using this discretization and verified the two positive eigenvalues of 0.3373 and 0.3634.
Solution 4 All the eigenvalues have negative real parts and are displayed in Figure 3.2. The eigenvalue with maximum real part is $-0.2826$.

Solution 5 This solution has a positive eigenvalue, namely 1.2812.

Solutions 6 and 7 These solutions have a positive eigenvalue, namely 0.4351.

In summary, the solutions, denoted as solutions 1, 2, and 4, have eigenvalues which have negative real parts yielding that they are stable.

3.3 Numerical verification

By time marching the system (1.1) without the maternal production terms, we numerically verified the local stability of the seven steady state solutions. This was accomplished by using a random perturbation of a solution of the boundary value problem as the initial condition as computing the steady state solution.

We first perturbed each steady state solution of size $[-0.05, 0.05]$. The results, summarized in Figure 3.3, demonstrate that the four solutions which have an eigenvalue with positive real part, as computed in Section 3.2, do not converge back to the un-perturbed steady state solution. They converge to one of the stable steady state solutions.

The three solutions which only have eigenvalues with negative real parts converge back to the un-perturbed steady state solution. By changing the size of the perturbation, we computed a local stability region for the three stable steady state solutions. In our tests, both solutions 1 and 2 converged to itself if the perturbation size was $[-0.23, 0.23]$ and solution 4 converged to itself if the perturbation size was $[-1.52, 1.52]$.

Hence we numerically verified that 3 of these 7 steady state solutions are locally stable, while the other 4 are unstable.
Figure 3.3: The steady state solutions by time-marching the system (1.1) without the maternal production terms. Randomly perturbations of the boundary value problem solutions serve as initial conditions. The perturbation size is $[-0.05, 0.05]$. Green: the boundary value problem solutions plus a random perturbation serving as the initial data. Red: the steady state by time-marching, at time $t = 100h$.

4 Role of the organizer

The organizer plays an important role in the selection of the steady state pattern in this multi-stability system. In this section, we numerically solved the full time-dependent system (1.1), with the maternal production terms. All molecules have zero initial concentrations in the simulations.

4.1 Organizer location

The numerical simulation results shown in Figure 4.1 demonstrate that the location of the organizer determines which stable steady state the system will converge to. When the organizer is located close to the right end of the interval, the time-marching solution converges to the stable steady state solution 1, and, if the organizer is located close to the left end of the interval, the time-marching solution converges to the stable steady state solution 2. The time-marching
solution converges to the stable steady state solution 4 if the organizer location is close to the middle of the interval.

4.2 Organizer size

The system is robust with respect to the change of the organizer size, which is consistent with the biological experiments [6]. In our simulations, we assume that the organizer is located at the right end, just as the wild type case [11]. We vary the organizer size from $\frac{1}{2}$ of the whole...
Figure 4.2: The evolution process of [LR] with different organizer size. The organizer region is presented right below each graph. In each graph, Green longdashed: the concentration of [LR] when $t = 3.5h$; Red dashed: the concentration of [LR] when $t = 50h$; Black solid: the concentration of [LR] when $t = 100h$.

domain to only $\frac{33}{256}$ of the domain, and study the effect on the steady state pattern. The results of these simulations are summarized in Figure 4.2 and show that the steady state solution is independent of the organizer size.
