Fig. S1: Fitting of CAM-B3LYP eigenvalue shift to SRC1-r2 eigenvalues for 3rd-row elements. A simple linear regression is used to obtain $\Delta \varepsilon$ in Eq. (6). Values are in Hartree.

S1
Fig. S2: Simulated XANES at the titanium K-edge, for the organotitanium complexes considered also in Fig. 6, using the same simulation parameters. As compared to CAM-B3LYP/CIS/def2-TZVPD, the TD-CAM-B3LYP/def2-TZVPD spectra require an additional shift of 76 eV to match experiment.
Fig. S3: Simulated XANES at the chlorine K-edge, for the organotitanium complexes considered also in Fig. 6, using the same simulation parameters. As compared to CAM-B3LYP/CIS/def2-TZVPD, the TD-CAM-B3LYP/def2-TZVPD spectra require an additional shift of 56 eV to match experiment.
Fig. S4: Simulated XES for CH$_3$Cl at the chlorine K-edge, using 200 states with a 1.0 eV Gaussian broadening. The CAM-B3LYP/CIS/def2-TZVPD spectrum is the same as in Fig. 7(b) and has been shifted to match experiment. The TD-CAM-B3LYP/def2-TZVPD spectrum requires a further shift of 45 eV.

Fig. S5: Simulated XES for H$_2$S at the sulfur K-edge, using 200 states with a 1.0 eV Gaussian broadening. The CAM-B3LYP/CIS/def2-TZVPD spectrum is the same as in Fig. 7(a) and has been shifted to match experiment. The TD-CAM-B3LYP/def2-TZVPD spectrum requires a further shift of 41 eV.
