The hydrogen molecule has been the benchmark system for quantum chemistry, and may provide a test ground for new physics. We present our high-resolution spectroscopic studies on the $X^1\Sigma_g^+$ electronic ground state rotational series^a and fundamental vibrational tones in molecular hydrogen. In combination with recent accurate *ab initio* calculations, we demonstrate systematic tests of quantum electrodynamical (QED) effects in molecules. Moreover, the precise comparison between theory and experiment can provide stringent constraints on possible new interactions that extend beyond the Standard Model.
