

ULTRAVIOLET PHOTOLYSIS OF CONDENSED-PHASE ACETYL CHLORIDE: VERIFICATION OF A CONCERTED ELIMINATION REACTION

BRAD ROWLAND, and WAYNE HESS, *Battelle Pacific Northwest National Laboratories, PO Box 999, Richland, WA. 99352, Mail Stop K2-14.*

Ultraviolet photolysis of condensed-phase acetyl chloride (CH_3COCl) produces ketene ($\text{H}_2\text{C}=\text{C}=\text{O}$) and HCl in a 1:1 dimer complex. The reaction mechanism sharply differs from the photodissociation of gas-phase molecules which produces chlorine and acetyl radical (CH_3CO) that further dissociates to CH_3 and CO. Two mechanisms of photodissociation of condensed-phase acetyl chloride have been proposed; concerted elimination and the caged abstraction. Thermodynamic analysis, polarized IR studies, and general spectroscopic observations of the photoproducts are used to show that the photodissociation of condensed acetyl chloride follows a concerted elimination mechanism.
