THE ROTATIONAL SPECTRA AND HYPERFINE CONSTANTS OF ZrS AND ZrO.

SARA A. BEATON AND MICHAEL C. L. GERRY, *Department of Chemistry, The University of British Columbia, 2036 Main Mall, Vancouver, British Columbia, Canada V6T 1Z1.*

The pure rotational spectra of ZrS and ZrO have been recorded using cavity Fourier transform microwave spectroscopy in the frequency range 9-26 GHz. The molecules were generated by laser ablation of a solid Zr rod with 0.05% of H_2S or O_2, respectively, in either argon or neon.

For ZrS, this is the first measurement of the pure rotational spectrum of the $X^1\Sigma^+$ state. Rotational transitions in the ground vibrational state were observed for all five $Zr^{32}S$ isotopomers and for the $^{90}Zr^{34}S$ isotopomer in natural abundance. Transitions in the first excited vibrational state were measured for the 3 most abundant isotopomers and a value for the equilibrium bond length calculated. For the $^{91}Zr^{32}S$ isotopomer nuclear hyperfine structure due to the zirconium nucleus was observed and values for $eQq(^{91}Zr)$ and $C_I(^{91}Zr)$ were determined.

The microwave spectra of the three most abundant isotopomers of $Zr^{16}O$ had been observed previously (1). The new results from the present work are the observations of the $J = 1 - 0$ transitions for the remaining two $Zr^{16}O$ isotopomers and three $Zr^{18}O$ isotopomers. In addition, the $v = 1$ $J = 1 - 0$ transition was measured for $^{90}Zr^{16}O$, allowing an accurate determination of r_e. ^{91}Zr nuclear hyperfine structure was observed for $^{91}Zr^{16}O$ and values of the hyperfine constants were determined. The hyperfine parameters for the two molecules are interpreted in terms of the electronic structure and chemical bonding.
