We report the observation and assignments of several series of transitions in CH₂DOH, including a new and intense series of Q-branch c -type transitions between the e_1 and o_1 torsional sub-states through high values of the rotational quantum number J . Other transitions assigned are c -type R-branch and P -branch transitions between these two sub-states and a -type lines within the e_1 and o_1 sub-states. The assignments were facilitated by initial analysis of the strong Q -branch series, as recorded by the FAsT Scan Sub-millimeter Spectroscopy Technique (FASSST). The assigned lines of CH₂DOH include the first in the sub-millimeter-wave and the first to possess high J -values. The completeness of the data generated by FASSST and the success of a simple power series analysis suggest that many parts of the spectrum of CH₂DOH may be far more tractable than previously believed. The data should be useful in the development of a full Hamiltonian and in the assignment of astronomical emission features.
