

## HIGH-RESOLUTION INFRARED SPECTROSCOPY OF HCN-Mg<sub>n</sub> CLUSTERS

PAUL L. STILES, KLAAS NAUTA, DAVID T. MOORE and ROGER E. MILLER, *Department of Chemistry,  
University of North Carolina, Chapel Hill, NC 27599.*

Rotationally resolved infrared spectra have been obtained for the first time for metal complex-adsorbate systems. In particular, bare Mg clusters have been grown in helium nanodroplets, to which are added a single HCN molecule. The IR spectra associated with the C-H vibrational band have been recorded for HCN-Mg<sub>n</sub> ( $n = 1 - 6$ ). The results indicate that there is a qualitative change in the HCN-Mg cluster bonding (highly non-additive) in going from  $n = 2$  to  $n = 4$ .
