ELECTRONIC STATE OF CoH: A PROBLEM RELATED TO THE SIZE-INCONSISTENCY OF THE MR-SDCI METHOD AND THE MIXING OF $^3\Phi$ AND $^3\Pi$

REI FUKUI, UMPEI NAGASHIMA, and TSUNEO HIRANO, *Grid Technology Research Center, Institute of Advanced Industrial Science and Technology, 6-9-3 Ueno, Taito-ku, Tokyo 110-0015, Japan*; HIROSHI TATEWAKI, *Computation Center and Institute of Natural Sciences, Nagoya City University, Nagoya 467-8501, Japan*; TAKESHI NORO AND KIYOSHI TANAKA, *Division of Chemistry, Graduate School of Science, Hokkaido University, Kita 10, Nishi 8, Kita-ku, Sapporo, 060-0810, Japan*.

The ground state of CoH has been determined experimentally as the $^3\Phi$ by the far-infrared magnetic resonance study,[a] and theoretically by *ab initio* methods.[b] However, MR-SDCI and MR-SDCI + Q *ab initio* molecular orbital calculations predicted that the lowest electronic state is $^5\Phi$. The size-consistent MR-ACPF method correctly predicted that $^3\Phi$ should be the ground state. As is previously reported by Tanaka *et al.*[c] on FeH, the controversial results in MR-SDCI may arise through truncation error inherent in the size-inconsistent MR-SDCI method.

Another difficulty is that we cannot clearly separate the Φ and Π states when CoH is treated under C_{2v} symmetry, not under its real symmetry of $C_{\infty v}$. The best results we obtained at the moment are: r_e = 1.528 Å, B_e = 7.291 cm^{-1}, and ω_e = 2005 cm^{-1} at the level of the MR-ACPF + relativistic correction using the Roos ANO (Co) and Dunning aug-cc-pVQZ (H) basis sets.
