

USING VIBRATIONAL SPECTROSCOPY TO STUDY CHEMICAL DYNAMICS IN GASES AND LIQUIDS

F. FLEMING CRIM, *Department of Chemistry, University of Wisconsin-Madison, Madison, WI 53706.*

Vibrational spectroscopy is a powerful tool for studying the chemical dynamics of vibrationally excited molecules. It provides insights into the couplings within a molecule and a description of the initial states prepared by excitation of fundamental or overtone vibrational transitions. The rovibrational structure of electronic transitions is often a means of determining populations of individual states of products and, hence, of inferring the detailed reaction dynamics. Experiments using ultrafast lasers are a means of probing chemical dynamics directly in the time domain, a particularly useful approach in solutions, and analysis of such experiments often rests on insights from frequency domain measurements.
