We discuss how the frequency-stabilized cavity ring-down spectroscopy (FS-CRDS) method enables high-precision and high-sensitivity measurements of shapes, intensities, as well as broadening and shifting parameters of absorption lines[a]. We illustrate the method's high spectral resolution by observation of sub-MHz wide Doppler-free saturation features in blended near-ir $H_2O$ spectra, and we present measurements and models of $H_2O$ and $O_2$ spectra that yield line parameters with sub%-level relative uncertainties.
