Conformational analysis of p-fluorophenol, phenetole and 1-methoxynaphthalene have been performed by measuring the laser induced fluorescence (LIF) excitation and dispersed fluorescence (DF) spectra under supersonic jet expansion. Vibronic analysis reveals existence of only one conformation of all the molecules. The findings are consistent with predictions of quantum chemistry calculations. The DF spectra measured following excitations to single vibronic levels display interesting features of vibronic mode mixing. Duschinsky analysis under harmonic approximations for vibrational modes in the two electronic states does not reproduce the observed spectral features. The systems exhibit low threshold of anharmonic interactions in the S1 state. The details will be presented in the talk.
