

HCO⁺ IN THE ENVELOPES OF OXYGEN-RICH STARS: EVALUATING THE ROLE OF ION-MOLECULE CHEMISTRY IN CIRCUMSTELLAR GAS

R.L. PULLIAM, L. M. ZIURYS, *University of Arizona, Steward Observatory, 933 N. Cherry Ave, Arizona.*

The role of ion-molecule chemistry is not well understood. Theory has predicted HCO⁺ as one of the most abundant detectable ions in oxygen-rich envelopes. However, there has never been a conclusive detection of HCO⁺ in any circumstellar sources. Here we present the results of millimeter and submillimeter observations of the cation HCO⁺ around evolved oxygen-rich stars. In recent observations, HCO⁺ has been detected in the circumstellar shell of the oxygen-rich supergiant VY Canis Majoris. Further observations were conducted around the oxygen-rich stars IK Tau, NML Cyg, W Hya and TX Cam. Abundances of this molecule in these sources and implications for circumstellar chemistry will be discussed.
