For the principal isotopomer $^{14}$N$^{32}$S$^{19}$F$_3$ of thiacyl trifluoride in the degenerate fundamental state ($v_3=1$), the hyperfine structure has been investigated in the $Q$-branch spectrum between 8 and 26.5 GHz using microwave Fourier transform waveguide spectrometers with a resolution limit of $\approx 30$ kHz. In addition to $I$-type doubling spectra and $I$-type resonance transitions with $\Delta k = l = \pm 2$, perturbation-allowed spectra were measured with $\Delta(k - l) = \pm 3$, $\pm 6$. The range in $J$ was from 13 to 61; for the lower states, $kl=\pm 3, \pm 2, \pm 1, 0, \pm 1$. For all the transitions, the hyperfine patterns observed are predicted to be doubles when only the nitrogen quadrupole Hamiltonian $H_N^Q$ is taken into account. Doubles were indeed measured for transitions with $\Gamma_{RV}=A_1 \leftrightarrow A_2$, where $\Gamma_{RV}$ is the rovibrational symmetry. However, when $\Gamma_{RV}=E \leftrightarrow E$, triplets and quartets were observed in addition to doubles. These anomalous hyperfine patterns are shown to be due to the $\Delta k = \pm 1$ and $\Delta k = \pm 2$ matrix elements of the fluorine spin-rotation Hamiltonian $H_F^S$ characterized by the fluorine spin-rotation constants $c(1) = c_{xx} + c_{yy}$ and $c(2) = c_{yy} - c_{xx}$, respectively. These terms in $H_F^S$ lift the parity degeneracy for $\Gamma_{RV}=E$. The rovibrational Hamiltonian $H_{RV}$ was adopted from an earlier partner study. A good fit to the hyperfine data was obtained with a standard deviation of 3.1 kHz. In the fitting process, 12 rovibrational parameters were varied, while the remaining constants in $H_{RV}$ were left at the values of Ref. (1). In addition, 8 hyperfine parameters were determined: four in $H_N^Q$, and two in $H_F^S$. It was found that $c(1) = 7.48(24)$ kHz and $c(2) = 2.423(22)$ kHz. This determination of $|c(1)|$ is the first to be reported based on frequency measurements. The key to the observation of the parity doubling lies in the severe mixing of the eigenvectors of basis vectors with several different values of $kl$ as a result of the clustering of rovibrational levels at low $K$.
