Phonological Theory

3

Contrast

The Classical Model:

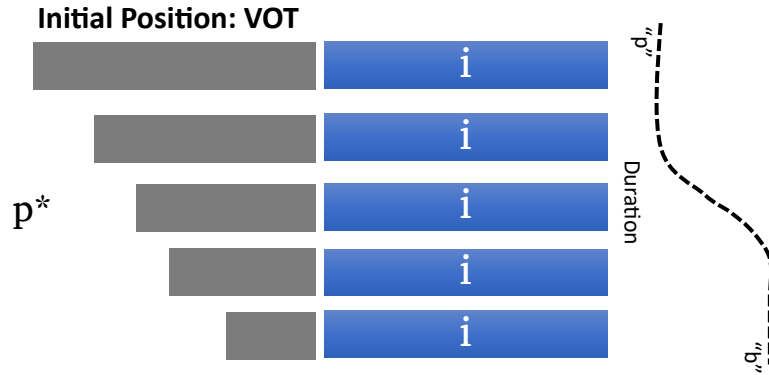

Words	Phonemes	Features						
"bit" vs. "bead"	Non-minimal contrast							
"bit" vs. "bid"	/t/ vs /d/	<table style="border-collapse: collapse;"> <tr> <td style="border-left: 1px solid black; border-right: 1px solid black; padding: 0 5px;"> +coronal +obstruent -sonorant -voice </td> <td style="border-left: 1px solid black; border-right: 1px solid black; padding: 0 5px;"> +coronal +obstruent -sonorant +voice </td> </tr> <tr> <td style="border-left: 1px solid black; border-right: 1px solid black; padding: 0 5px;">.</td> <td style="border-left: 1px solid black; border-right: 1px solid black; padding: 0 5px;">.</td> </tr> <tr> <td style="border-left: 1px solid black; border-right: 1px solid black; padding: 0 5px;">.</td> <td style="border-left: 1px solid black; border-right: 1px solid black; padding: 0 5px;">.</td> </tr> </table>	+coronal +obstruent -sonorant -voice	+coronal +obstruent -sonorant +voice
+coronal +obstruent -sonorant -voice	+coronal +obstruent -sonorant +voice							
.	.							
.	.							
"spit" vs. "sbit"	Lack of contrast							

4

Diagnostics of Contrast

Word Recognition | Phoneme Recognition: Categorical Perception Experiment

“pea” vs. “bee”

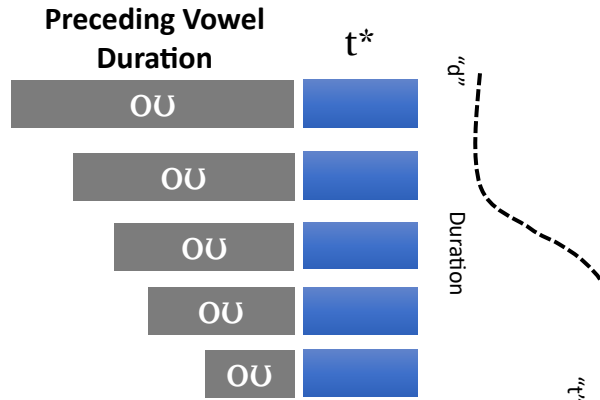

5

Diagnostics of Contrast

Word Recognition | Phoneme Recognition: Categorical Perception Experiment

“coat” vs. “code”

6

Allophony

What is the underlying contrastive feature?

<ul style="list-style-type: none"> • /p/ → [p^h] /' __ V • /b/ → [p] /# __ 	<p><u>pat/bat:</u> /p/ has longer VOT than /b/, word-initially</p>	<p>/b/ ≠ [b]</p> <p>/χ/ ≠ [b]</p>
<ul style="list-style-type: none"> • /p/ → [b] /'V __ V 	<p><u>rapid/rabid:</u> /p/ has longer closure duration than /b/, post-stress, word medially</p>	
<ul style="list-style-type: none"> • /b/ → [p] / __ # • /p/ → [p̄] / __ # 	<p><u>tap/tab:</u> Vowel preceding /b/ is longer than vowel preceding /p/, in coda position</p>	<p>Paradox 1: phonetic symbol system is identical to phonological symbol system</p>

7

7

Allophony

Allophony implies normalization
That has to be “undone”

What is generated

What is stored

What is generated

What is stored

8

8

Trading Relations

The (lack of) invariance problem

- Longer VOT changes category membership
- shorter following vowel shifts category boundary to shorter stop
Summerfield (1981); Miller & Volaitis (1982)
- longer preceding vowel shifts category boundary to longer stop
Summerfield (1981); Miller & Volaitis (1982)

“b” i

“p” i

“p” i

i # “b” i

9

9

Cues that could be exploited by listeners

Word-Final stops:

- duration of voicing
- intensity of voicing
- Aspiration
- F0 contour
- length of vowel formant transitions with respect to steady state duration
- F1 offset frequency
- speed of jaw lowering
- jaw offset position

Continuous “trade offs”

.../acoustic/articulatory/phonetic/ phonological/...

But why does allophony occur in the first place?

Paradox 2:
Contrast should prevent allophony!

Fitch 1981; Crowther & Mann 1992; Van Summers 1987
cf. Bailey & Summerfield 1980

10

10

Specification and Underspecification

Variation is allowed on dimensions that are not specified

Control of articulation is evidence for specification

[±voice]

[voice]

or not

∅

- aspirated/un-aspirated
- long VOT/short VOT
- Released/un-released
- voiced/voiceless/partially voiced

voicing present

voicing present when context is appropriate

p#d
VpV

What are the Underlying Features?

Articulatory rather than acoustic?
Fitch 1981; Crowther & Mann 1992; Van Summers 1987; Bailey & Summerfield 1980

English:
[spread glottis] vs. ∅
("p" vs. "b")
Kim 1970; Iverson & Salmons 1995

Regressive assimilation to
[spread glottis]
Crowther & Mann 1992; Jansen 2004

Russian:
[voice] vs. ∅
("b" vs. "p")
Keating 1984; Beckman et al 2013

of passive voicing
Beckman et al 2001

Specifications are not necessarily parsimonious in real human languages

[spread glottis] vs. [voice]
Beckman et al 2001

Important Implications: [wake up here]

- Categorical perception does not entail a *necessarily* contrastive feature, only a possible one (when all other information is absent). See Trading Relations.
- There is a very large number of possible allophonic rules (at least on the acoustic side).
- Allophonic rules imply normalization
- The relationship between underspecification and variation implies an inverse relationship between contrast and allophony
- Specification is likely to be continuous, and not necessarily parsimonious [this is an empirical question]

13

13

Sound Change

14

14

The Actuation Paradox Paradox 3

A direct result of the normalization assumption

Normalization: No Change

>

Lack of Normalization: Change

In collusion with the discrete sequencing assumption $k+\text{æ}+t$

15

15

The Actuation Paradox

Allophonic Vowel Nasalization Rule [synchronic]:

$$V \rightarrow \tilde{V} / _N$$

Loss of coda nasals [diachronic]:

$$N > \emptyset / _.$$

Loss of allophonic rule/predictability [synchronic]

$$V \rightarrow \tilde{V} / _??$$

$$V \rightarrow V / _??$$

Minimal Pair Test

$$/N/ \text{ vs. } /Ñ/$$

Paradox 3:
loss of allophonic context
should lead to
loss of allophone

16

16

Models of Sound Change

Phonetically ambiguous/outlier tokens are discarded

- As a result of competing contrastive categories

(Blevins & Wedel 2009; Wedel 2006, 2007; Tupper 2014)

- In speech mode, but not non-speech mode

(Garrett & Johnson 2013)

- For some (neurotypical) individuals, but not others

(Yu 2013)

- Except when misparsing occurs

(Kirby 2014)

Sometimes you normalize
Sometimes you don't

17

17

No Normalization = Change?

Exemplars: episodic memory traces

Paradox 4:
unnormalized tokens
are not consistent with
allophonic rules

18

18

No Normalization = Change?

Exemplars: episodic memory traces

Paradox 4:
unnormalized tokens
are not consistent with
allophonic rules

19

19

No Normalization = Change?

Exemplars: episodic memory traces

Paradox 4:
unnormalized tokens
are not consistent with
allophonic rules

Paradox 5:
the same symbol systems
are used for acoustic
and articulatory
representations!

20

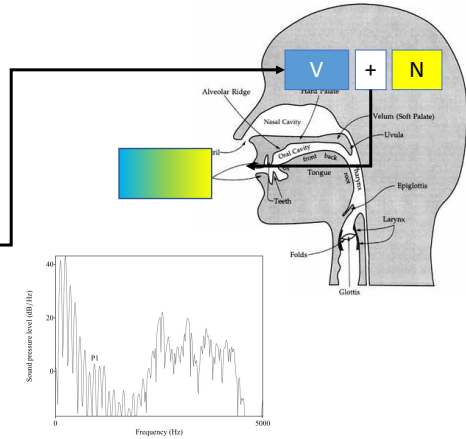

20

Why do allophones exist?

Coarticulation!

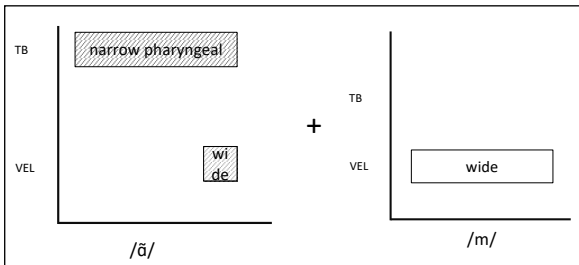

Browman & Goldstein 1988

Why do allophones exist?

Coarticulation!

Perception \Leftrightarrow Production

Hypotheses about articulations

Model (Morley 2019):

- Ambiguity in normal speech processing
- Competing Hypotheses (Parses) for each acoustic input
- Parse depends on acoustic variables
- Not nasal loss, but nasal merger

There is an inverse correlation between degree of nasalization on vowel and length of nasal (Beddor 2013).

23

23

Important Implications: [wake up here]

- Speech perception must involve:
 - mapping acoustic input to articulatory categories (targets)
 - Segmentation of ambiguous input
- Lack of normalization implies lack of allophony
- Unless allophony is an emergent property of articulation
- Incremental change is possible with distributions of stored, unnormalized acoustic tokens (exemplars)

24

24

Speech Processing

25

25

Is Normalization Required?

1. Longer vowel creates expectation for following voiced (rather than voiceless) stop:

ou 

Sounds like "coat"

ou 

Sounds like "code"

2. Nasalized vowel spliced into non-nasal syllable sounds more like lower vowel (higher F1): Krakow et al 1988

sẽnd  → /ɛ/

sẽnd } s ẽ d  → /æ/

sɛd }

3. Expected degree (and direction) of place-of-articulation assimilation facilitates word recognition: Gow and McMurray 2007

gɹɪn bɪn , gɹɪn dɔg >> gɹi n dɔg , gɹi n bɪn

26

26

Is Normalization Required?

Acoustic Normalization:

- attributing distributed acoustic cues to individual (source) segments
- adjusting acoustic cue values based on context

[sɛnd] ↪ /ɛ/

ou d ↪ /ou/

gɪn^w bɪn ↪ /n/

Implies a more abstract/invariant underlying representation that must be closely matched

e.g., Gow (2002); Beddor et al. (2002); Kirby (2014); McMurray et al (2011)

27

27

Is Normalization Required?

- Trading Relations/Categorical Perception/(In)Variance Problem
- Expectation/Compensation/Prediction

- No acoustic cues are absolute
- Classification depends strongly on other cues present, context
- Previous input, current context, current knowledge generate predictions about upcoming material
- listeners are highly sensitive to correlations among acoustic cues

28

28

The Phonological Parser

Vowel Silence Frication

gɹ					"gray ship"	
gɹ					"great ship"	
gɹ					"gray chip"	
gɹ					"great chip"	

Repp et al. (1978)

29

29

The Phonological Parser

gɹ ɪp

#

t

ert.

Ambiguous: silence followed by start of ʃ

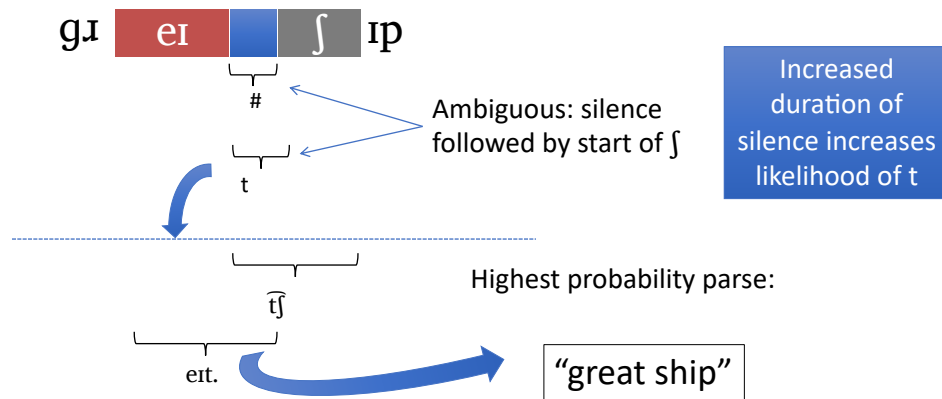

Given the length of the silence relative to eɪ
And the length of t relative to ʃ:
#ʃ is highest probability parse

"gray ship"

30

30

The Phonological Parser

31

31

Is Normalization Required?

Rather than matching abstract acoustic symbols, speech perception can be described as choosing the optimal phonological parse, that is, the likeliest string of **articulatory symbols** that would result in the observed acoustic input

Remember Paradox 5!

32

32

Is Normalization Required?

Rather than matching abstract acoustic symbols,
speech perception can be described as choosing the optimal
phonological parse, based on:

- All available contextual information
- Self-consistency

Local Optimum

- Relative feature values
- In most cases, from a small candidate set (~ 2 words)
- In most cases, involving local comparisons within a 2-3 segment window

Krakow et al. 1988

38

38

A World without Normalization?

Classification/Identification

Phoneme-level
(assuming fixed segmentation)

The diagram shows a lateral view of a human brain with several phoneme labels: /ε/ in a brown circle on the left side and /æ/ in a red circle on the right side. Five thought bubbles are connected to the brain by dashed lines: a light brown bubble with 'ε + n?', a brown bubble with 'ε + d?', a red bubble with 'æ + d?', a pink bubble with 'æ + n?', and a blue bubble with 'normal en'. A dotted arrow points from a box containing 'ε̃ n' to an ear icon on the left.

Krakow et al. 1988

39

39

A World without Normalization?

Classification/Identification

Phoneme-level
(assuming fixed segmentation)

The diagram is identical to slide 39, but the box on the left contains 'ε̃' followed by an empty white box. The thought bubbles are: a light brown bubble with 'ε + n?', a brown bubble with 'ε + d?', a red bubble with 'æ + d?', a pink bubble with 'æ + n?', and a blue bubble with 'weird e/ai'.

Krakow et al. 1988

40

40

A World without Normalization?

Storage

Phoneme-level

The diagram shows a lateral view of a human brain with numbered regions. Two overlapping circles are placed on the brain: a brown circle labeled /ɛ/ and a red circle labeled /æ/. A dotted line connects the ear to the /ɛ/ circle, and a dashed line connects the ear to the /æ/ circle. To the left of the ear, there are two boxes: an orange box containing the phonetic symbol /ɛ/ and a white box containing the letter 'n'.

41

41

A World without Normalization?

Storage

Phoneme-level

The diagram shows a lateral view of a human brain with numbered regions. Two overlapping circles are placed on the brain: a brown circle labeled /ɛ/ and a red circle labeled /æ/. A dotted line connects the ear to the /ɛ/ circle, and a dashed line connects the ear to the /æ/ circle. To the left of the ear, there is an orange box containing the phonetic symbol /ɛ/ and a white empty box. Below the ear, the text "I said I would do the dishes" is written, with the word "said" highlighted in an orange box.

"I said I would do the dishes"

42

42

A World without Normalization?

Production

Phoneme-level

No allophonic rule. But gestural coordination routines/motor plans that are subject to external sources of variation:
Speaking rate, word predictability/frequency, ease of articulation...

43

43

The Model (implementation is crucial)

- Synchronic variation is the result of normal speech processing
- Sound change is present in synchronic variation
 - allophony of continuously fluctuating degree
- Allophones are emergent from the interaction of
 - articulatory specification
 - gestural coordination
 - acoustic specification

44

44

The Model

- Speaker/Listeners store:

acoustic targets

check/constrain output

articulatory targets

for production to be possible

unnormalized acoustic experiences

short-term adaptation/accomodation

incremental sound change

45

45

The Model

- Speaker/Listeners store acoustic targets, articulatory targets, and unnormalized acoustic experiences

Short-term adaptation/accommodation

Incremental sound change

- Degree of specification for each acoustic feature depends on its informativity wrt the contrast

Phonological Specification

46

46

The Model

Perception

- Acoustic input is evaluated by simulation, using underlying articulatory categories

Local context sensitivity

Parsing window

Avoids normalization

- Best overall acoustic similarity determines category membership

Avoids normalization

47

47

The Model

Perception

- Acoustic input is evaluated by simulation, using underlying articulatory categories
- Best overall acoustic similarity determines category membership
- Targets are directly affected by changes to the distribution of stored acoustic exemplars

Incremental sound change

Avoids actuation paradox

48

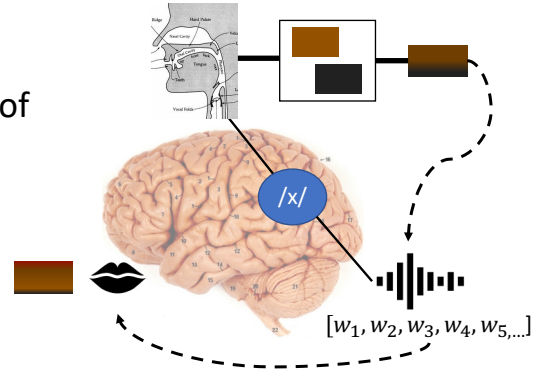

48

The Model

Production

- Articulatory targets are perturbed by: production error and gestural overlap of adjacent units
- Ultimate acoustic realization is constrained by degree of specification of each individual feature

Emergent Allophony

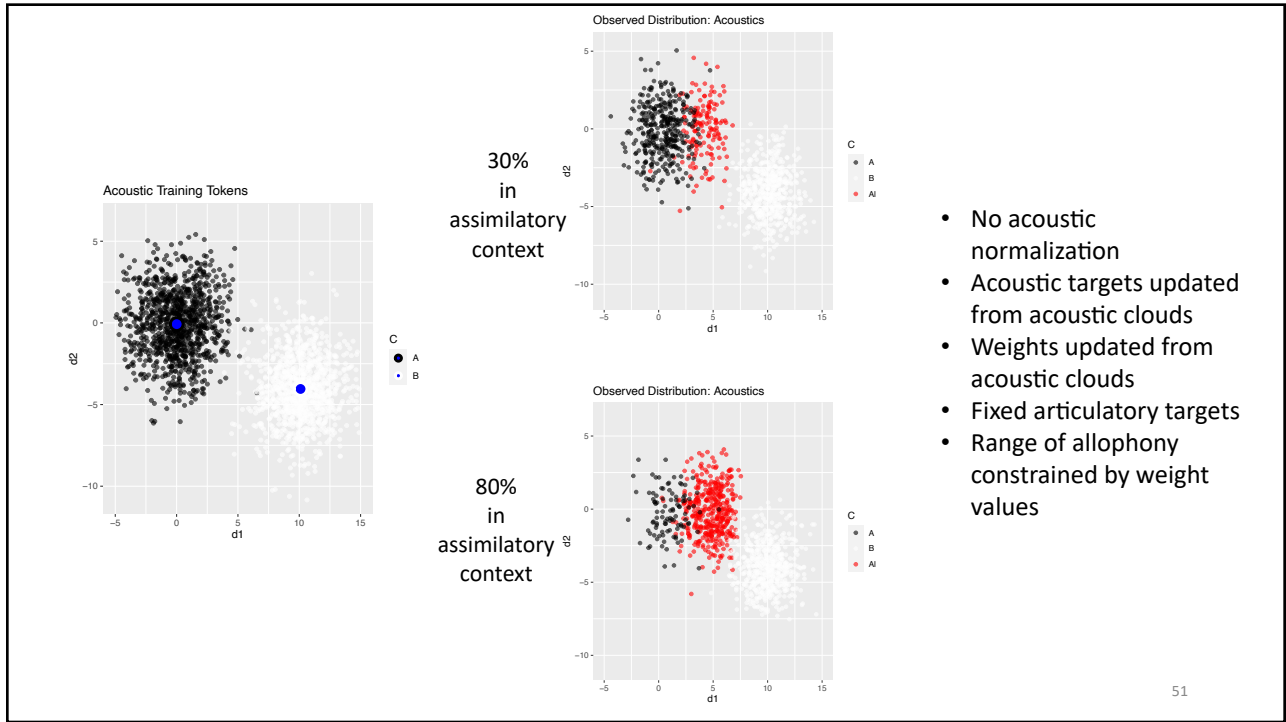

49

49

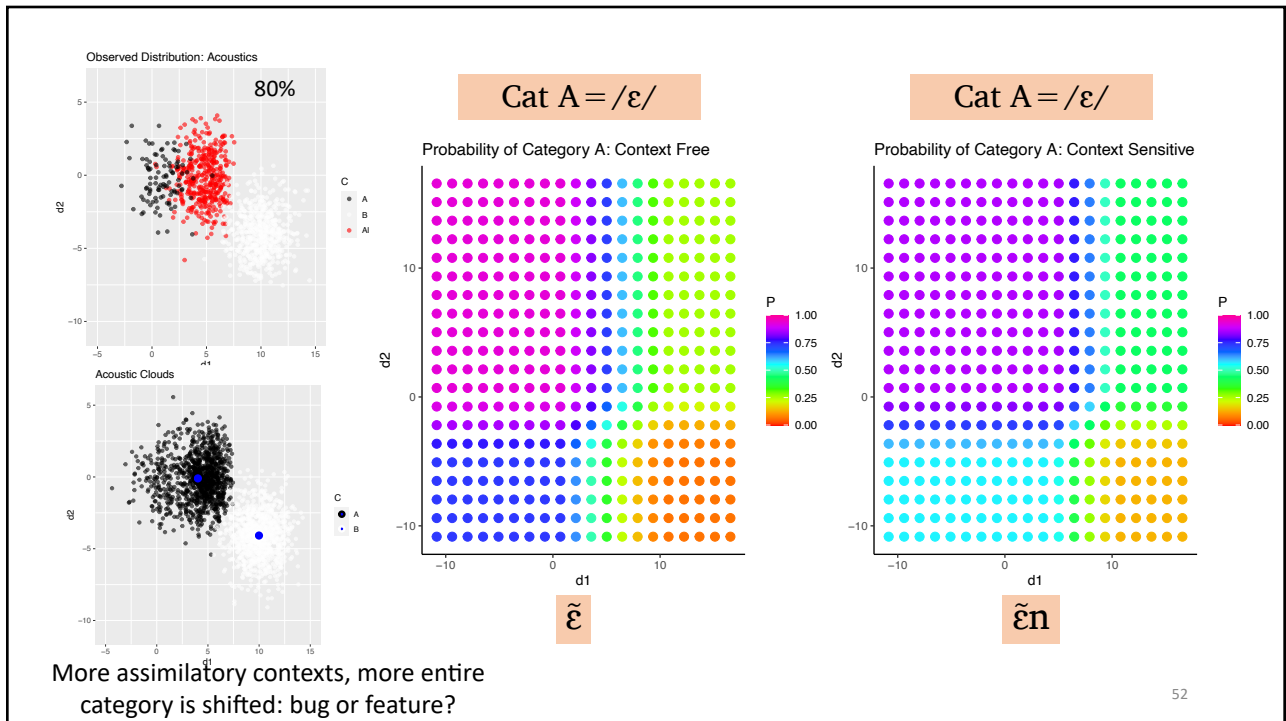

Thank You!
